About This Workshop

• Description

• Learn more about Android application security

• Understand tools and techniques to exploit Android applications

• Get skills to perform reverse engineering, static and dynamic tests, binary analysis and other conventional attack vectors

• Comprises both demos + hands-on exercises

• Hands-on with InsecureBankv2 and other custom applications
Workshop Focus

- To help you make the most of this workshop, these thermometers give you an idea of the technical level and content focus.
Security conferences
WHO AM I?

• Leads Mobile Security Testing CoE at Security Innovation

• Mobile and Embedded application pentesting

• Knowledgeable in all phases of the secure software development life cycle (SDLC)

• Security Speaker and Trainer at multiple conferences such as BlackHat, OWASP, Brucon, Defcon, ClubHack etc.

• Research work has been published at PacketStorm, Exploit-db, SecurityXploded, ClubHack, Pentest Magazine etc.
WHO AM I WITH?

• Founder and CEO, Attify

• Main role - Break and Exploit any Mobile application

• Leads 75+ Mobile pentests in past 3 years

• Security Speaker and Trainer at numerous security conferences such as BlackHat, Defcon, OWASP AppSec, Toorcon, HackInParis, Phdays, ClubHack, Nullcon etc.

• Authored a book on mobile security titled “Learning Pentesting for Android Devices”
Workshop Agenda

• Module 1: Mobile Security Introduction
• Module 2: Android Primer
• Module 3: Android Security Basics
• Module 4: Android Vulnerabilities
Module 1: Mobile Security Introduction

- Why Android?
- Types of Android Applications
- Testing Challenges for Mobile Applications
- Mobile Security Threat Landscape
- Attack Surfaces

Fandango, Credit Karma Settle FTC Charges that They Deceived Consumers By Failing to Securely Transmit Sensitive Personal Information

Mobile Apps Placed Credit Card Details, Credit Report Data, Social Security Numbers at Risk

FOR RELEASE
March 28, 2014

Two companies have agreed to settle Federal Trade Commission charges that they misrepresented the security of their mobile apps and failed to secure the transmission of millions of consumers’ sensitive personal information from their mobile apps.

The FTC alleged that, despite their security promises, Fandango and Credit Karma failed to take reasonable steps to secure their mobile apps, leaving consumers’ sensitive personal information at risk. Among other things, the complaints charge that Fandango and Credit Karma disabled a critical default process, known as SSL certificate validation, which would have verified that the apps’ communications were secure.

As a result, the companies’ applications were vulnerable to “man-in-the-middle” attacks, which would allow an attacker to intercept any of the information the apps sent or received. This type of attack is especially dangerous on public Wi-Fi networks such as those at coffee shops, airports and shopping centers.

Fandango
The Fandango Movies app for iOS allows consumers to purchase movie tickets and view show times, trailers, and reviews. According to the FTC’s complaint, the Fandango Movies app assured consumers, during checkout, that their credit card information was stored and transmitted securely. Despite this promise, for almost four years—from March 2009 until February 2013—the company disabled SSL certificate validation and left consumers that used its app to make mobile ticket purchases vulnerable to man-in-the-middle attacks.

The complaint alleges that Fandango could have easily tested for and prevented the vulnerability, but failed to perform the basic security checks that would have caught the issue. In addition, the complaint charges that Fandango failed to have an adequate process for receiving vulnerability reports from security researchers and other third parties, and as a result, missed opportunities to fix the vulnerability.

Credit Karma
The Credit Karma Mobile app for iOS and Android allows consumers to monitor and evaluate their credit and financial status. In its complaint, the FTC alleges that Credit Karma assured consumers that the company followed “industry-leading security precautions,” including the use of SSL to secure consumers’ information. Despite these promises, the company disabled SSL certificate validation and left consumers that used its credit-monitoring app vulnerable to man-in-the-middle attacks.

According to the FTC, Credit Karma could have easily prevented the vulnerability with basic tests, but did not perform an adequate security review of its iOS app before release. Even after a user warned Credit Karma about the vulnerability in its iOS app, the company failed to test its Android app before launch. As a result, one month after receiving a warning about the issue, the company released its Android app with the very same vulnerability. The complaint charges that Credit Karma failed to appropriately test or audit its apps’ security and failed to oversee the security practices of its application development firm.

Settlements
The settlements require Fandango and Credit Karma to establish comprehensive security programs designed to address security risks during the development of their applications and to undergo independent security assessments every other year for the next 26 years. The settlements also prohibit Fandango and Credit Karma from misrepresenting the level of privacy or security of their products and services.

18 firms sued for using privacy-invading mobile apps

Facebook, Apple, Twitter are among those charged in class action suit with surreptitiously taking user data

Facebook, Apple, Twitter, Yelp and 14 other companies have been hit with a lawsuit accusing them of distributing privacy-invading mobile applications.

The lawsuit was filed by a group of 13 individuals in the United States District Court for the Western District of Texas earlier this week. The suit charges 18 companies with surreptitiously gathering data from the address books of tens of millions of smartphone users.

“The defendants -- several of the world’s largest and most influential technology and social networking companies -- have unfortunately made, distributed and sold mobile software applications that, once installed on a wireless mobile device, surreptitiously harvest, upload and illegally steal the owner’s address book data without the owner’s knowledge or consent,” the lawsuit alleged.

The lawsuit seeks a permanent injunction against such data collection and the destruction of all personal data collected by mobile application vendors so far.

Most of the plaintiffs are from Austin and describe themselves in the complaint as users of Apple’s iPhone users Android-powered handsets.
Mobile Security Introduction
We are Here to Avoid This…

Trustwave Sued by Casino Operator Over Breach Investigation

By Eduard Kovacs on January 18, 2016

Las Vegas-based casino operator Affinity Gaming has accused Chicago-based IT security firm Trustwave of failing to properly investigate and contain a payment card breach suffered by the company in 2013.

A complaint filed by Affinity Gaming with the district court of Nevada in December alleges that Trustwave misrepresented its ability to perform an adequate investigation, failed to identify the true source of the breach, and falsely assured the casino operator that the breach had been contained.

In December 2013, Affinity Gaming reported suffering a security breach in which malicious hackers penetrated its payment card systems. The incident was investigated by Trustwave, whose employees analyzed the casino operator's systems for more than two months in an effort to determine the extent of the breach, find its source and contain it.

According to Affinity's complaint, at the end of its investigation, Trustwave informed the company that the malware was removed from its systems and that the breach was contained.

A few months after Trustwave completed its investigation, Affinity Gaming called in professional services company Ernst & Young to conduct penetration testing. In mid-April, penetration testers identified suspicious activity associated with a piece of malware that Trustwave was supposed to remove as part of its investigation.

Types of Android Applications
Module 1: Mobile Security Introduction

• Why Android?
• Types of Android Applications
• Testing Challenges for Mobile Applications
• Mobile Security Threat Landscape
• Attack Surfaces
Mobile Security Introduction

Mobile Testing Challenges - Application Complexity

• Browser-Based Applications
  • Easier to test
  • Using a normal browser, you can change the browser user agent, and the server will send the mobile version
  • Use an emulator/device to read persistent cookies or local data storage
  • All the attacks for traditional web applications apply to browser-based mobile applications

• Native Applications
  • Need a real device or an emulator (Android) / simulator (iOS) to do testing
  • The OS and frameworks are optimized, resulting in poor code readability when reverse engineering binaries
  • Tools are harder to use
  • Not all web based attacks are valid to native applications
    • E.g.: in many cases XSS is not a valid case for a pure native application which does not have a web front-end

• Hybrid Applications
  • Challenges from both browser-based and native applications!
  • Need a real device or an emulator/simulator to do testing
  • All native application test cases + web application test cases are valid for hybrid applications
Mobile Security Introduction

Mobile Testing Challenges - Platform Complexity

- The large number of permutations of OS, hardware, networks, configurations, and software adds extra complexity to security testing.
- It is challenging to test on a platform with limited memory, storage, and power.
- Multiple releases of operating systems.
- Different hardware/chipsets
  - Different hardware sensors, cameras, etc.
- Complex configurations.
- Different networks
  - Wi-Fi is easy to test with proxy.
  - 3G or 4G network traffic is hard to intercept + Illegal in many countries.
Module 1: Mobile Security Introduction

- Why Android?
- Types of Android Applications
- Testing Challenges for Mobile Applications
- Mobile Security Threat Landscape
- Attack Surfaces
Mobile Security Introduction Mobile Security Threat Landscape

Image Source: https://drawception.com/pub/panels/2013/12-2/22a95WLG4-8.png
Module 1: Mobile Security Introduction

- Basic Tools for Mobile Application Security Testing
- Why Android?
- Types of Android Applications
- Testing Challenges for Mobile Applications
- Mobile Security Threat Landscape
- Attack Surfaces
Mobile Security Introduction Mobile Avenues of Attack

- Sensitive information stored in the APK client Binary
- Vulnerabilities between APP <-> Server
- Vulnerabilities between APP <-> 3rd Party Servers
- Vulnerabilities related to data stored by the Android Operating System
- Vulnerabilities related to data stored in application sandbox
- Static Vulnerabilities in the APP
- Vulnerabilities in the APP during runtime
- Vulnerabilities between APP <-> APP
- Vulnerabilities in the Web Server
- Vulnerabilities in the Remote Datastores
Mobile Security Introduction
Mobile Device Infrastructure and Trust Boundaries

• The mobile environment is very complex
  • This is particularly notable in a BYOD environment
• Many trust boundaries have to be considered from an application development standpoint
• Many opportunities for failure
• Modified from: Mobile OWASP Top 10
  http://www.youtube.com/watch?v=pQAIwyXAZBk
Workshop Agenda

- Module 1: Mobile Security Introduction
- **Module 2: Android Primer**
- Module 3: Android Security Basics
- Module 4: Android Vulnerabilities
Module 2: Android Primer

- Understanding the Android Package Structure
- Android Debug Bridge
- Android File Structure
- Android Rooting Background
- Understanding Android Components
Android Primer
Understanding the Android Package Structure

• Application are developed using Android Studio

• Distributed as .apk files through the Google Play Store

• Applications are signed using Developer certificate

• No DRM signing by Google
Understanding the Android Package Structure
TASK

• Unzip *InsecureBankv2.apk* to find the corresponding resource files

• Find *classes.dex* from the extracted folder

• Can you read the actual contents of *classes.dex* file?

• Can you read the *AndroidManifest.xml* file?
Module 2: Android Primer

• Introducing the Android IDE and SDK
• Understanding the Android Package Structure
• **Android Debug Bridge**
• Android File Structure
• Android Rooting Background
• Understanding Android Components
The Android OS helps control and enforce security

- **Android Debug Bridge (adb)** is a command line tool that lets you communicate with an emulator instance or with a connected Android device
  - Used for testing; uploading payloads and tools

- In a non-rooted device, certain parts of the directory structure are blocked
  - Analogous to Linux, where `sudo` must be run to gain access
  - Rooting a device allows root access to those directories

- The Android emulators are rooted by default
  - The Developer has access to everything
Android Primer
Android Debug Bridge (ADB)
TASK

• Launch an avd

• Run `ps` to view the current process details.
  • What weird fact do you notice?
Module 2: Android Primer

- Introducing the Android IDE and SDK
- Understanding the Android Package Structure
- Android Security Model
- Android Debug Bridge
- Android File Structure
- Android Rooting Background
- Understanding Android Components
Android Primer
Android File Structure

A LOT TO SEE HERE ...
Android Primer

Android File Structure - Important Locations

• `/data/data` : All applications data installed by user
• `/data/app` : APKs of applications installed by user
• `/system/app` : System Applications
• `/data/system` : Files such as gesture.key
• `/data/local/tmp` : Writeable (without root)
Pulling application from device

- `ps`
- `pm path <package name>`
- `adb pull <device app path> <local directory>`
TASK

• Pull the apk corresponding to “com.android.phone”
Module 2: Android Primer

- Introducing the Android IDE and SDK
- Understanding the Android Package Structure
- Android Debug Bridge
- Android File Structure
- Understanding Android Components
Android Primer
Android App Components

- Activities
- Services
- Intents
- Content Providers
- Broadcast Receivers
Android Primer
Identifying Android app components

• Start any application analysis with AndroidManifest.xml

• Look for components such as `<activity>`, `<provider>`, `<receiver>` and so on.

• Use the android:name element to determine the exact name of the component, which will be used for later analysis
android:label="@string/app_name"
android:theme="@android:style/Theme.Holo.Light.DarkActionBar"
</activity>

<activity
    android:name=".LoginActivity"
    android:label="@string/app_name"
    android:theme="@style/LoginTheme">
    <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>

<activity
    android:name=".FilePrefActivity"
    android:label="@string/title_activity_file_pref"
    android:windowSoftInputMode="stateVisible|adjustResize|adjustPan">
</activity>

<activity
    android:name=".DoLogin"
    android:label="@string/title_activity_do_login">
</activity>

<activity
    android:name=".PostLogin"
    android:exported="true"
    android:label="@string/title_activity_post_login">
</activity>
<activity>
Android Primer

Android App Components - Activities

• Visual Screens of an Android application

• Contains of different layouts

• Anything you could interact with

• Wallet applications
Android Primer
Android App Components - Services

• Background events in an Android application

• Eg: Downloading files / Playing Music
Android Primer

Android App Components - Intents

• To bind different android components

• Used to perform different kind of actions

• Changing activities, invoking activities in another application, starting an action etc.

• Intent Filters
Android Primer

Android App Components – Content Providers

• Storing, Retrieving and Sharing application data

• Acts as a middle layer

• SQLite, XML, PlainText

• With the prefix “content://”
Android Primer

Android App Components - Broadcast Receivers

• Receives broadcast from various events

• Could be from the phone or another app

• Used by a lot of malwares
Workshop Agenda

- Module 1: Mobile Security Introduction
- Module 2: Android Primer
- **Module 3: Android Security Basics**
- Module 4: Android Vulnerabilities
Module 3: Android Security Basics

- Reversing Android Applications – Level 1
- Reversing Android Applications – Level 2
- Proxying Android Traffic
Android Security Basics
Reversing Android Applications - Level 1

• Using APKTool

• Wrapper around smali and baksmali

• apktool d appname.apk
TASK

• Unzip the contents of *Fortinet Client* binary

• Is the *AndroidManifest.xml* file readable?

• Use *apktool* to decompile the application binary

• View the contents of the */res* folder

• View the contents of the *smali* files and see if it makes any sense
Examining Smali files

• Example Java code:
  
  ```java
  if (flag == 1)
      flag = 2
  else
      flag = 3
  ```

• Equivalent Smali code:
  
  ```smali
  const/4 v1, 0x1
  if-ne v0, v1, :cond_0
  const/4 v2, 0x2
  move v0, v2
  goto :goto_0
  :cond_0
  const/4 v2, 0x3
  move v0, v2
  :goto_0
  ```
Examining Smali files

- \texttt{v0}, \texttt{v1}, \texttt{v2}, \texttt{p0}, \texttt{p1}, \texttt{p2}: Used for indicating registers

- \texttt{Iput}: Used to put values

- \texttt{Const}: Used for indicating constants

- \texttt{Invoke-virtual} or \texttt{invoke-method}: Used to indicate method call
Module 3: Android Security Basics

- Reversing Android Applications – Level 1
- Reversing Android Applications – Level 2
- Proxying Android Traffic
Android Security Basics
Reversing Android Applications – Level 2

• Apktool is not fun
• Smali is not easy to read
• Welcome – dex2jar and JADX
Android Security Basics
Reversing Android Applications - Level 2
Android Security Basics
Reversing Android Applications

• What to Look for:
  • Hardcoded secrets
  • Hardcoded keys
  • Client-side dependencies
  • Hardcoded private information
  • Hardcoded developer information
TASK

• Reverse Engineer the Fortinet client to get the java source code
Module 3: Android Security Basics

- Reversing Android Applications – Level 1
- Reversing Android Applications – Level 2
- Proxying Android Traffic
Android Security Basics

Proxying Android Traffic
Android Security Basics
Proxying Android Traffic
Setting up the Test Environment

1. Configure Burp to Listen
2. Export Burp certificate
3. Install Burp certificate on device
4. Install Proxy front-end and Configure Device to Route
5. WIN !!
Parameter tampering is an attack where the data in messages exchanged between the client and server are modified by the attacker. The attacker can view and tamper with requests on the client, or at any location between the client and the Trust Boundary. The tampering can occur in either direction, even with a secure connection.
Workshop Agenda

• Module 1: Mobile Security Introduction
• Module 2: Android Primer
• Module 3: Android Security Basics
• Module 4: Android Vulnerabilities
Module 4: Android Vulnerabilities

• Exploiting Local Storage
• Exploiting Weak Cryptography
• Exploiting Android Components
• Exploiting Side Channel Data Leakage
• Patching Android Applications
• Root Detection and Bypass
• Exploiting Backup functionality
Exploiting Local Storage

- There are several ways to read local data:
  - **On a rooted device**
    - SSHDroid + WinSCP/ssh/sftp/PuTTY
      - SSHDroid installs an SSH server on the device
  - **On a non-rooted device**
    - `adb shell`
    - Use the Monitor tool
      - Go to the tools directory of the SDK, and run `monitor` or `DDMS` (deprecated)
      - Click on the file Explorer tab to use a GUI to navigate
      - There are buttons to push and pull files
Exploiting Local Storage
Android Shared Preference Files

• Shared Preference files are similar to Android property files
  • Shared Preferences are used for storing key-value pairs of primitive data types
  • For example, Shared Preferences are used to store user’s settings and application data

• Extension:
  • .xml

• Location:
  • /data/data/<package-name>/shared_prefs/<prefs_name>.xml

• Tools
  • Notepad
Exploiting Local Storage
Android Shared Preference Files
Exploiting Local Storage
Android SQLite Database

• Description
  • SQLite is an open-source database that does not need to have a server
    • Provides robust persistent data storage
    • Native SQL database within the complete control of application
  • Examine these databases to look for sensitive data, such as user settings, application data

• Extension:
  • .sqlite

• File Location:
  • /data/data/<package-name>/databases/

• Tools
  • Windows/Mac – SQLite Browser (http://sourceforge.net/projects/sqlitebrowser/)
  • Windows/Mac/Linux – SQLite Studio (http://sqlitestudio.pl/)
Exploiting Local Storage
Android SQLite Database
Exploiting Local Storage
Android SD Card Data

- Description
  - Examine the files on the SD Card to look for sensitive data, such as user settings, application data
  - There are no file permissions on SD Card
  - Any application can read the contents of the SD Card
- Extension:
  - Multiple extensions
- File Location:
  - `/sdcard/`
- Tools
  - Use any file explorer to read SD card data
TASK

• Find the sensitive information stored in property files, database files and flat files by the given application.

• You can use “find”.

Module 4: Android Vulnerabilities

- Exploiting Local Storage
- **Exploiting Weak Cryptography**
- Exploiting Android Components
- Exploiting Side Channel Data Leakage
- Patching Android Applications
- Root Detection and Bypass
- Exploiting Backup functionality
Exploiting Weak Cryptography
TASK

- Find the crypto vulnerability in Fortinet Client
Module 4: Android Vulnerabilities

• Exploiting Local Storage
• Exploiting Weak Cryptography
• Exploiting Android Components
• Exploiting Side Channel Data Leakage
• Patching Android Applications
• Root Detection and Bypass
• Exploiting Backup functionality
Exploiting Android Components

• Activity Manager

• Could be used to launch applications and pass data while launching

• Could also be used to launch specific activities within the application
Exploiting Android Components

- Activities
- Services
- Content Providers
- Broadcast Receivers
Exploiting Android Components
Activities

```
am start -n <packagename>/.<activityname>
```
Exploiting Android Components

• Activities
• Services
• Content Providers
• Broadcast Receivers
Exploiting Android Components

Services

adb shell am startservice -n "com.example.application/.SomeServiceName"
Exploiting Android Components

• Activities
• Services
• **Content Providers**
• Broadcast Receivers
Exploiting Android Components
Content Providers
Exploiting Android Components

• Activities
• Services
• Content Providers
• **Broadcast Receivers**
Exploiting Android Components
Broadcast Receivers

adb shell am broadcast -a <boardcastname>-n <packagename>/<broadcast> --es <extras> <extras>
Module 4: Android Vulnerabilities

- Exploiting Local Storage
- Exploiting Weak Cryptography
- Exploiting Android Components
- Exploiting Side Channel Data Leakage
- Patching Android Applications
- Root Detection and Bypass
- Exploiting Backup functionality
Exploiting Side Channel Data Leakage

• Vulnerabilities Include:
  • Copy Paste Buffer
  • Android Keyboard Cache
  • Android Log Files
Exploiting Side Channel Data Leakage Copy Paste Buffer

• Android has a common copy-paste buffer for all the applications
  • Data in this buffer is shared across different applications
• When copy/paste is allowed on sensitive fields like credit card numbers, SSN, usernames, etc., the data in the buffer is available to other applications
  • This could result in the leakage of sensitive information
• The copied text is stored locally
Exploiting Side Channel Data Leakage
Copy Paste Buffer
Exploiting Side Channel Data Leakage

Android Keyboard Cache

• Keystrokes are logged to help with auto-correction and form completion
• New words are cached as part of the Android auto-correction feature
  • It is turned on by default for all textfields except password fields
• When auto correction is allowed on sensitive fields like credit card numbers, SSN, usernames, etc., this could allow sensitive information to be stored as keywords on the device
• The keywords are stored locally at /data/data/com.android.providers.userdictionary/databases/user_dict.db
Exploiting Side Channel Data Leakage
Android Keyboard Cache
Exploiting Side Channel Data Leakage

Android Log Files

- Android maintains a centralized logcat of all the apps and device logs
- Android uses circular buffers for log messages
  - `adb logcat [-b buffer_name]` dumps the logs to `stdout`
    - `main` is the default buffer
    - `radio` contains radio/telephony related messages
    - `events` contains events-related messages
    - The `-f <filename>` parameter dumps the buffer to `<filename>`
- Can be accessed with READ_LOGS permission before 4.1
- Logcat permission has now changed to `signature|system|development`
Exploiting Side Channel Data Leakage
Android Log Files
Module 4: Android Vulnerabilities

- Exploiting Local Storage
- Exploiting Weak Cryptography
- Exploiting Android Components
- Exploiting Side Channel Data Leakage
- Patching Android Applications
- Root Detection and Bypass
- Exploiting Backup functionality
Patching Android Applications

- APK files contain a file called **classes.dex** which is the app bytecode for the Dalvik VM

  - The bytecode in **classes.dex** file can be disassembled into “Android assembler” (**.smali**)
    - It’s not like Java, but it is pretty high-level compared to “real” assembly code
    - Unless the developer ran code through an obfuscator like ProGuard or DexGuard, method and member names are preserved
    - This means it may be possible to understand and modify the code
    - Then you can recompile the code 😊

- Patching applications can be done to bypass authentication rules or root detection routines

- This is something that people do when…
  - Pirating games, etc.
  - Bypassing root detection or SSL Pinning checks
  - Removing authentication checks, etc.
Patching Android Applications
Patching Android Applications
Patching Android Applications
Signing in Android

- `keytool -genkey -v -keystore <<keystore_name>> - alias <<your_key_alias>> -keyalg RSA -keysize 2048 - validity <<no_of_days>>`

- `jarsigner -verbose -sigalg MD5withRSA -digestalg SHA1 -keystore <<keystore_name>> <<.apk file>> <<your_key_alias>>`

- `jarsigner -verify -verbose <<path_to_apk>>`
Patching Android Applications
TASK

• Decompile the cocon_apk.apk file using a combination of dex2jar and Apktool

• Make the necessary changes to enable the key in the cocon.smali file

• Recompile the application

• Sign the application

• Reinstall the application
Module 4: Android Vulnerabilities

- Exploiting Local Storage
- Exploiting Weak Cryptography
- Exploiting Android Components
- Exploiting Side Channel Data Leakage
- Patching Android Applications
- Root Detection and Bypass
- Exploiting Backup functionality
Detecting a Rooted Device

- Developers may want to detect if a device has been rooted for a variety of reasons
  - For example, they may not want the application to be run on a rooted device

- There are many ways to detect a rooted device
  - Default files and configurations that are found on rooted devices (not able to access on non-rooted devices due to permissions)
    - Release-keys tags, Over the Air (OTA) certificates
  - Installed files and packages present on rooted devices
    - Superuser.apk, su
  - Changed directory permissions
    - Rooted devices will have certain directories that are writable
    - /data is readable
    - If certain commands run, that can be an indication of a rooted device

- Not all methods work consistently
  - Every developer has their own “secret sauce” for detected a rooted device
private boolean doesSUexist() {
    Process process = null;
    try {
        process = Runtime.getRuntime().exec(new String[] {"/system/xbin/which", "su"});
        BufferedReader in = new BufferedReader(new InputStreamReader(process.getInputStream()));
        if (in.readLine() != null) return true;
        return false;
    } catch (Throwable t) {
        return false;
    } finally {
        if (process != null) process.destroy();
    }
}
Root Detection and Bypass
Detecting a Rooted Device

```java
private boolean doesSuperuserApkExist(String s) {

    File rootFile = new File("/system/app/Superuser.apk");
    Boolean doesexist = rootFile.exists();
    if(doesexist == true)
    {
        return(true);
    }
    else
    {
        return(false);
    }
}
```
Root Detection and Bypass
Detecting a Rooted Device

• Check for the BUILD tag
  • cat /system/build.prop | grep ro.build.tags
    • ro.build.tags=release-keys

• Check for Over The Air (OTA) certificates
  • ls -l /etc/security/otacerts.zip
    • -rw-r--r-- root root 1125 2016-05-16 15:29 otacerts.zip

Module 4: Android Vulnerabilities

- Exploiting Local Storage
- Exploiting Weak Cryptography
- Exploiting Android Components
- Exploiting Side Channel Data Leakage
- Patching Android Applications
- Root Detection and Bypass
- Exploiting Backup functionality
Exploiting Backup functionality

• If Backup is enabled on the application, the sensitive data stored by the application is also backed up.
• Android allows backups and restoration of its data [without root]
• Attacker could take the backup of an app, modify the contents and restore it back again
• Lastpass Vulnerability (Patched now, found by Chris John Riley)
